Candidate: 15199

March 2018

Problem 1

Particle nature of the photon

a1.

Comptons scattering formula can be written on the form

$$\Delta\lambda = \lambda_s - \lambda_i = \lambda_C(1 - \cos\Theta), \quad (1)$$

where λ_i is the incident photon, λ_s is the scattered photon, $\cos\Theta$ is the angle between the horizontal and the scattered photon, $\lambda_C = h/(m_e c) = 2.43 \times 10^{-3} \text{ nm}$ is the *Compton wavelength for the electron* where h is Plancks constant, m_e is the electron mass and c is the speed of light. Figure 1 shows a schematic of the setup.

a2.

Using Comptons formula, we can find the angle by

$$\Theta = \cos^{-1} \left(1 - \frac{\Delta\lambda}{\lambda_C} \right) = \cos^{-1} \left(1 - \frac{0.0749 \text{ nm} - 0.0709 \text{ nm}}{0.00243 \text{ nm}} \right) \approx 130^\circ, \quad (2)$$

which seems like a reasonable result considering the graphs given in the problem.

a3.

$$\frac{\lambda_C}{\lambda_i} \quad (3)$$

Visible light yields wavelengths in the range $380 \text{ nm} - 750 \text{ nm}$. X-rays have shorter wavelengths and thus

Figure 1: Compton scattering.

Wave nature of the neutron

b1.

Average energy is given by

$$\langle E \rangle = \frac{3}{2} k_B T, \quad (4)$$

where T is the temperatur in Kelvin and k_B is Boltzmanns constant. $25^\circ = 298K$ and thus

$$\rightarrow \langle E \rangle = 1.5 \times (1.38 \times 10^{-23} m^2 kgs^{-2} K^{-1})(298.15K) \approx 6.17 \times 10^{-21} J. \quad (5)$$

Momentum is found from the particles kinetic energy

$$\langle E \rangle = \frac{1}{2} m v^2 \rightarrow \langle p \rangle = \sqrt{2 \langle E \rangle m_n}, \quad (6)$$

where m_n is the neutron mass

$$\rightarrow \langle p \rangle = \sqrt{1 * 6.17 \times 10^{-21} J \times 1.67 \times 10^{-27} kg} \approx 4.54 \times 10^{-24}. \quad (7)$$

Finally we can find the wavelength by using the *deBroglie relation*

$$\lambda = \frac{h}{p} \rightarrow \lambda = \frac{6.32 \times 10^{-34} J}{4.54 \times 10^{-24}} \approx 1.30 \times 10^{-10} m \approx 0.1 nm \quad (8)$$

,

where h is Plancks constant.

b2.

Bragg diffraction is given by

$$n\lambda = 2d \sin \Theta, \quad (9)$$

where n is a positive integer and λ is the *wavelength of the incident wave*. Maximum intensity is given at $n = 1$, and thus

$$\Theta_{max} = \sin^{-1} \frac{\lambda}{2d} \quad (10)$$

We want $|\Delta\lambda|/\lambda \leq 10\% = 1/10$.

By using (1) and (9) we get write

$$\frac{|\Delta\lambda|}{\lambda} = \frac{\lambda_C(1 - \cos \Theta)}{2d \sin \Theta} \leq \frac{1}{10} \quad (11)$$

$$\rightarrow \frac{h(1 - \cos \Theta)}{mc2d \sin \Theta} \leq \frac{1}{10} \rightarrow \tan \frac{\Theta}{2} \leq \frac{mcd}{5h} \rightarrow \Theta = 2 \tan^{-1} \frac{mcd}{5h} \quad (12)$$

Problem 2

Radioactive α -decay

a.

We find A by *normalizing the wavefunction*. $|\Psi(x, 0)| = \Psi^* \Psi$, where Ψ^* is the complex conjugate and thus, the imaginary part will vannah and the integral becomes

$$|\Psi(x, 0)|^2 = |A|^2 \int_{-\infty}^{+\infty} e^{-(x-x_0)/2a^2} = 1. \quad (13)$$

Substituting $u = x - x_0 \rightarrow du = dx$ and $\lambda = 1/(2\pi a^2)$ yields the following standard integral that can be found in Rottmann

$$|A|^2 \int_{-\infty}^{+\infty} e^{-\lambda u} du = |A|^2 \sqrt{\frac{\pi}{\lambda}} = |A|^2 \sqrt{2\pi a^2} = 1 \rightarrow A = \left(\frac{1}{2\pi a^2} \right)^{1/4} \quad (14)$$

which gives

$$\Psi(x, 0) = \left(\frac{1}{\sqrt{2\pi a^2}} \right)^{1/4} e^{-(x-x_0)/4a^2} e^{ikx} \quad (15)$$

b.

We need to find general solutions for the three regions for which the particle can exist. As figure 2 shows, we have that $0 \leq E \leq V_0 \rightarrow E > 0$, so we're dealing with *scattering states*.

For $(0 \leq x \leq x_1)$, $V(x) = 0$ and the time-independent Schrödinger equation reads

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} = E\psi \rightarrow \frac{d^2\psi}{dx^2} = -k^2\psi, \quad k \equiv \frac{\sqrt{2mE}}{\hbar} \quad (16)$$

which general solution is

$$\psi(x) = Ae^{ikx} + Be^{-ikx}. \quad (17)$$

For $(x_1 \leq x \leq x_2)$, $V(x) = V_0 \rightarrow E < V_0$, so we will get complex solutions and thus the time-independent Schrödinger equation reads

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} + V_0\psi = E\psi \rightarrow \frac{d^2\psi}{dx^2} = -q^2\psi, \quad q \equiv i\kappa, \quad \kappa \equiv \frac{\sqrt{2m(V_0 - E)}}{\hbar} \quad (18)$$

which general solution is

$$\psi(x) = Ce^{iqx} + De^{-iqx} = Ce^{-\kappa x} + De^{\kappa x} \rightarrow Ce^{\kappa x} + De^{-\kappa x}. \quad (19)$$

(I switched the constants C and D to make the equation consistent with my sketch.)

For $(x \geq x_2)$, the general solution is similar to the left region, however, the latter term in the sum represents a wave coming in from the right and thus is omitted from the equation

$$\psi(x) = Fe^{ikx}. \quad (20)$$

To summarize, the general solution of the three regions are

$$\psi(x) = \begin{cases} Ae^{ikx} + Be^{-ikx} & , \quad 0 \leq x \leq x_1 \\ Ce^{\kappa x} + De^{-\kappa x} & , \quad x_1 \leq x \leq x_e \\ Fe^{ikx} & , \quad x \geq x_1 \end{cases} \quad (21)$$

c.

We need to look at the boundary conditions for $\psi(x)$ and $d\psi/dx$. The derivatives of ψ will have the following form

$$\frac{d\psi(x)}{dx} = \begin{cases} ik(Ae^{ikx} - Be^{-ikx}) & , \quad 0 \leq x \leq x_1 \\ q(Ce^{\kappa x} + De^{-\kappa x}) & , \quad x_1 \leq x \leq x_e \\ ikFe^{ikx} & , \quad x \geq x_1 \end{cases} \quad (22)$$

Figure 2: Potential barrier as given in the problem.

Figure 3: To find boundary conditions, we offset the potential barrier by $-x_1$. We also set $A = 1$, the *incomming wave*, $B = r$, the *reflected wave* and $F = t$, the *transmitted wave*.

Because the barrier is not located at $x = 0$, we need to offset it by $-x_1$ which will give the following boundary conditions

$$\psi_1(0) = \psi_2(0), \quad (23)$$

$$\psi_2(\Delta x) = \psi_3(\Delta x), \quad (24)$$

$$\frac{d}{dx}\psi_1(0) = \frac{d}{dx}\psi_2(0) \text{ and} \quad (25)$$

$$\frac{d}{dx}\psi_2(\Delta x) = \frac{d}{dx}\psi_3(\Delta x), \quad (26)$$

$$(27)$$

which will give

$$1 + r = C + D, \quad (28)$$

$$Ce^{q\Delta x} + De^{-q\Delta x} = t, \quad (29)$$

$$ik(1 - r) = q(C - D) \text{ and} \quad (30)$$

$$q(Ce^{q\Delta x} - De^{-q\Delta x}) = ikte^{ik\Delta x}, \quad (31)$$

$$(32)$$

where I have set $A = 1$, the *incomming wave*, $B = r$, the *reflected wave* and $F = t$, the *transmitted wave*.

Now we are left with four equations. We need to solve for t . This is straight forward and left as an exercise to the reader as it is trivial (I'm just kidding! Here it is!).

We start with (29), solving for C

$$C = \frac{te^{ik\Delta x} - De^{-q\Delta x}}{e^{q\Delta x}} \quad (33)$$

Inserting (33) into (31) yields

$$q(te^{ik\Delta x} - 2De^{-q\Delta x}) = ikte^{ik\Delta x}. \quad (34)$$

Solving for t yields

$$t = \frac{2qDe^{-z\Delta x}}{z^*}, \quad (35)$$

where we have introduced the variables $z \equiv q + ik$ and $q^* \equiv q - ik$. Next, eliminate r from (28) and (30) to get

$$ik(1 - r) = q(C - D), \quad (36)$$

which after some manipulations yields

$$C = \frac{Dz^* + 2ik}{z}. \quad (37)$$

Setting (33) = (37) yields

$$te^{-z^*\Delta x} - De^{-2q\Delta x} = \frac{Dz^* + 2ik}{z}, \quad (38)$$

wich gives, by solving for D

$$D = \frac{tze^{-z^*\Delta x} - 2ik}{z^* + ze^{-2q\Delta x}}. \quad (39)$$

Put (39) into (35)

$$tz^* = \frac{tze^{-z^*\Delta x} - 2ik}{z^* + ze^{-2q\Delta x}} e^{-z\Delta x} \quad (40)$$

which, if we solve for t yields

$$t = \frac{2ike^{-z\Delta x}}{ze^{-(z^*+z)\Delta x} - \frac{z^*}{2q}(z^* + ze^{-2q\Delta x})} \quad (41)$$

$$= \frac{1}{\frac{ze^{-z^*\Delta x}}{2ik} - \frac{z^*e^{-z\Delta x}}{4ikq}(z^* + ze^{-2q\Delta x})} \quad (42)$$

$T = |t|^2$ and thus

$$T = \left(\frac{1}{\frac{ze^{-z^* \Delta x}}{2ik} - \frac{z^* e^{-z \Delta x}}{4ikq} (z^* + ze^{-2q \Delta x})} \right)^2 \quad (43)$$

I have skipped many steps, however, my calculations by hand is attached at the end of the document.
